assembly instructions for [system 76 10 799 00](#)

Version 14.12.2017

**If you can install and time a stock ignition and possess basic mechanical skills, you can install a Powerdynamo!
If you never have worked on your ignition, better have it done by someone who knows.**

Powerdynamo can not monitor the compliance to those instructions, nor the conditions and methods of installation, operation, usage and maintenance of the system. Improper installation may result in damage to property and possibly even bodily injury. Therefore we assume no responsibility for loss, damage or cost which result from, or are in any way related to, incorrect installation, improper operation, or incorrect use and maintenance. We reserve the right to make changes to the product, technical data or assembly and operating instructions without prior notice.

IMPORTANT:

Please read these instructions fully and carefully before starting work on your motorcycle

Please bear in mind that [any modification of the material as well as own repair attempts which have not been agreed with Powerdynamo may result in a loss of warranty. Do not cut off wires. This leads to a loss of reverse polarity protection and often results in damage to electronics.](#) Also, please take note of the information provided on the information page for this system. Check that what you have bought really corresponds to the motorcycle you have. Wrong ignition settings may damage your engine and even hurt you during kickstart (violent kickbacks). Be careful during the first test runs. If needed change settings to safer values (less advance). During assembly check carefully that the [rotor \(flywheel\) does not touch the stator coils or anything else](#), which may happen due to various circumstances and lead to severe damage.

Designated use

This system is designated to replace stock dynamo/alternator & ignition systems in vintage and classic motorcycles [whose engine characteristics have not been modified aftermarket](#). This system is not a tuning system and it will not bring significant increases in engine output. It does however significantly enhance roadworthiness and comfort by offering better lighting, better function of side indicators and horn and, compared with the aging stock systems, increased reliability. As our system does not tamper with engine characteristics it does not increase emission of gaseous pollutants and noise. In most cases emission of pollutants should even be reduced due to better combustion. If used as designated the system therefore will not normally infringe the existing legal status of the motorcycle (this statement is valid for Germany, for other countries, please check locally against your road licensing regulations). This system is not suitable for use in competition events. If used other than the designated way, warranty will be voided and it might well be that you do not obtain the desired results or, worst you lose legal roadworthiness.

The charging system is only suitable for use with rechargeable 12V (6V systems 6V) lead-acid batteries with liquid electrolyte or sealed lead-acid batteries, AGM, Gel. [It is not suitable for use with nickel-cadmium, nickel-metal-hydride, lithium-ion or any other types of rechargeable or non rechargeable batteries.](#)

This is a [replacement system and not a copy of the stock material](#). The parts in this system therefore look

different and might fit differently (notably ignition coil and regulator) requiring some adaptation by you.

During assembly imperatively start with assy of engine based parts to see that those really fit before you start fitting the external parts. In many cases customers assemble those first and thereby often [modify them in breach of warranty](#) which renders them unfit for renewed sale. [Replacing old ignition systems is not a matter of taking something from a supermarket shelf as there have been very many types, versions and possibly unknown aftermarket modifications which harbour plenty of room for error.](#)

Our systems are **NOT tested for use with third party electronic devices (such as GPS, mobile phones, LED lighting etc) and may cause damage to such parts.** Possibly existing [electronic tachometers](#) will not work with the new system. Read our [information for suitable solutions](#). Possibly existing safety switches and electronic valve controls are not supported. It might be that your motorcycle was originally equipped with an ignition that did limit top speed for legal reasons. The new system does not have such a facility, so check your legal situation beforehand.

If you have no expertise for the installation have it done by an expert or at a specialist's workshop. Improper installation may damage the new system and your motorcycle, possibly even lead to bodily harm.

Before you order a system, please check whether a [puller tool](#) for the new rotor is included in the kit. If not, better order it at the same time. You might want to order light [bulbs](#), [fuse](#), horn, [flasher unit](#) etc. Never use anything other than the recommended puller tool to pull the new rotor again. Damage to the rotor as a result of use of other tools or methods is not covered by warranty.

The rotor is sensible to blows (including during transport). Before assembly, please always check for damage (on rotor without magnet plastification try to push the magnets aside with your fingers). After impact the glued in magnets might have broken loose, sticking to the rotor solely by magnetic force, so that one does not notice right away. During engine run the damage would be considerable. Before placing the rotor onto the engine, please make sure that its magnets have not collected any metal objects such as small screws, nuts and washers. That equally would lead to severe damage.

If you have access to the Internet, best view those instructions online. You get larger and better pictures by clicking onto them and possibly updated information. System list at <http://www.powerdynamo.biz>

DC System: You should have received those parts:

- stator (pre-assembled)
- rotor
- electronic ignition coil, high tension cable and blue kill wire
- regulator/rectifier
- 3 screws M4, 2 wire binders

Note that the stator is only loosely fixed to its base, as you will have to disengage it for assembly.

INFO [Pictures in the document may \(online\) be enlarged by clicking onto them](#)

AC System: You should have received those parts:

- stator (pre-assembled)
- rotor
- electronic ignition coil, high tension cable and blue kill wire
- AC regulator
- 3 screws M4, 2 wire binders

Note that the stator is only loosely fixed to its base, as you will have to disengage it for assembly.

INFO Pictures in the document may (online) be enlarged by clicking onto them

Note

This system fits more than one engine and those possible have differently sized stock rotor fastening nuts (which you continue to use). As we do not know the engine you are installing into, we have added various washers for this nut (that may reach from M10 to M16), knowing that not all of them are usable in your application.

To disengage the new rotor again, you need a puller M27x1,25 (order-no.: 99 99 799 00 **-Not provided!**-

Note: the stock puller for your Motoplat or SEM does not suit. It has M26x1.5!).

Note: Never use a claw puller, a hammer or any other device, that will shake the magnets off.

Make sure your motorcycle rests securely on her stand, preferably on an elevated work bench and that you have good access to the generator side of the engine.

Take the stock Motoplat/SEM system off off. You will need a puller M26x1.5.

Disconnect the wires from the old magneto and the old ignition coil and regulator and take off these parts now no longer needed (In KTM you will need the cable holder clamp).

Take the woodruff key from the crank. You will not need it anymore. Please do not forget to do so, otherwise you will have trouble later on in the assembly.

Remark: This woodruff key does not actually hold your rotor on the shaft, this is done by the cone. It simply guides to the correct setting which will now be otherwise achieved.)

For more information see [KB entry here](#)

Make sure the taper is sound and clean.

Unfasten the 3 screws M4x25, which hold the stator on its base but do not pull the wire completely through the plate to avoid setting the stator back in the wrong position.

Place the new stator base onto the engine block. Fasten the plate with the base plate screws (please use the supplied ones, they need to be fairly flat).

The system fits to various engines. You will need to set the plate in such a way that the wire shows towards the wire exit of the casing.

Please note that the system will fit various KTM differing in direction of wire exit. Always place the plate in such a way that the wire shows towards the wire exit at the engine. Take the new stator base.

The base plate has - somewhat to the left of the wire opening - a small red dot which indicates the ignition marking.

As this dot will not be visible any more once you have placed the rotor, you need to transpose the marking onto the outer casing as indicated in the picture below left.

Some makeshift tool the thickness of the original woodruff key can help this a lot as it will ensure you go from center (below right)

Now place the stator coil back onto the base (which you have securely tightened to the crankcase!).

Take care not to damage the wires. The stator has to snap in rather sharply. If it sets softly, you have probably crimped a wire underneath!

Make sure that the inner opening of the stator unit slots evenly over the elevated fixing rim of the base plate - otherwise the coil will sit lopsided and will touch the rotor, damaging it. Also, wires underneath may be damaged leading to shortcircuit.

Screw the coil down with the 3 screws M4x25 and tighten.

In KTM engines secure the cable with the stock cable holder or some small pipe clamp as shown here.

As space at the magneto side is quite confined and as there might have been changes on the crank or you might possibly have some engine type for which the system does not really fit, we urgently recommend

to **undertake a small clearance check of the stator to the rotor** with a small piece of plasticine at the highest point. Put a small amount of plasticine (if not at hand, use chewing gum) on the highest point of the large black coil and press the rotor on by hand. Then lift the rotor carefully off again (using the puller makes this easier) and check thickness of the plasticine. This might be something like 2mm with rotor not tightened.

More info [see knowledgebase here](#)

Also carefully check that the rotor does not touch the cable.

Further, you must check the end of the crank taper against the bottom surface of the puller hole of the rotor. With some engines the taper may be slightly above the bottom of the opening which will prevent the nut fastening the rotor securely if not detected and cured by adding a shim or in bad cases a distance piece. The rotor would slip in that case, making timing unsuitable.

The picture here exaggerates the problem in order to demonstrate what we mean.

2 shims and a spacer are included in the delivery.

Have a look at the new rotor (flywheel). You will find on its circumference a small lasered on line. That is an ignition marking. It is durable, but not well visible, so better highlighten it with some marker pen.

Place the rotor provisionally (hand tight only) onto the shaft in order to get some leverage on the crank when bringing it into ignition position.

Take the spark plug out to avoid compression during this work. Once you have set the crank into correct firing position, take the rotor carefully off again (use puller!), making sure not to change the position of the crank. If that happens redo the procedure.

Now you will have to time the ignition by setting the rotor in such a position that

with piston at ignition moment the marking on the rotor aligns with the transposed stator marking on the outer casing.
(marking on rotor in picture below amplified for illustration)

For where timing (firing) moment is, consult your manufacturers manual. Should you not have any guidance at all try with 2mm BTDC. For a KTM 565 e.g. this is 2.1-2.2mm i.e. 0.084-0.088" or 16.5-17°, for the 454 2,3-2,4mm (18,7-19,1°).

Finally,

fasten the rotor carefully with the original nut (for KTM this is KTM part 51030028100, note: M12x1, LH threading) and the stock washer plus, so needed the mentioned shims. Torque as per KTM manual is 54-59Nm. Should the taper protrude as shown above, place the shims first as the stock washer might have a too small inner diameter.

Fasten the ignition coil and the regulator on the frame of the motorcycle, best there, where the original coil was. The fastening holes of the new coil unfortunately do not match the old Motoplat coil exactly.

We are sorry for this. More detail [see KB entry here](#)

Connecting Powerdynamo alternator to lighting circuit - Versions with DC and with AC regulator

The 2 black wires running from the stator coil carry the voltage for lights, horn, flashers etc. They have nothing to do with ignition.

This voltage (something between 10 and 50 volts AC) has however to be stabilized (regulated) and for most uses rectified into direct current (DC) as it primarily is alternating current (AC).

For this we offer different regulators:

Attention: Any confusion between plus and minus (with the DC versions) leads to immediate destruction of the regulator. This will not constitute a warranty case as it is negligence! One can recognize a burnt regulator mostly by its sharp smell.

DC Regulator: [DC regulator with built in smoothing condenser \(73 00 799 50\)](#)

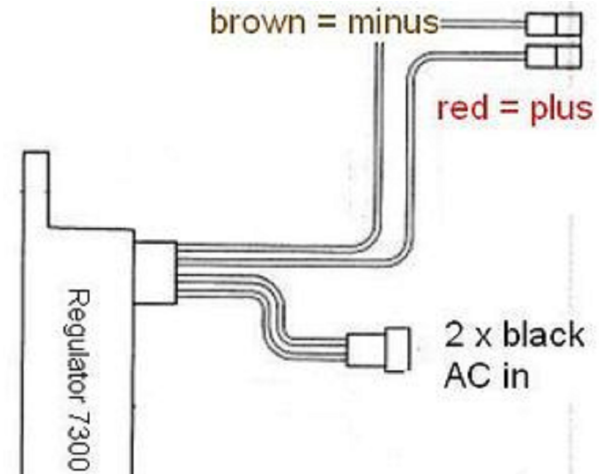

- the 2 black (sw) wires are the AC input from the alternator (as it is AC it does not matter which black to which black)
- the red (rt) wire is the 12V DC output plus
- the brown (br) wire is ground, internally connected to housing

AC Regulator: [AC regulator \(70 36 799 50\)](#)

- the 2 black (sw) wires are the AC input from the alternator (as it is AC it does not matter which black to which black)- the outer pins are used
- from the center pin and ground you connect you have regulated AC, feeding into [AC consumers](#)
- There is no way for a charge control (already not: because there is no battery).

Connect the parts as shown in [wiring diagram 71ik_102](#):

*	To facilitate wire exit through the often small openings in the engine casing, the plastic plug of the generator's wiring that leads to the ignition coil has not been put onto the wire terminal. You should place the plug there only once all has been properly installed on the engine side.	
	<p>Look for the ignition coil with its female plug and the two wires (red and white).</p> <p>Put the provided 2-position plug housing onto this plug and insert the two wires (red and white) from the generator. Make sure that the terminals engage securely in the housing and that you connect:</p> <ul style="list-style-type: none"> ■ white to white ■ red to red 	
<p>Should you need (or want) to get the terminals out of the plug housing again, enter a paper clip from front next to the terminals and push the little barb aside. Than pull the wire out.</p>		
<p>The brown wire from the new generator with the round eye terminal has to be screwed directly to the holder frame of the ignition coil (ground).</p> <p>Take note! disrespecting is the most frequent cause for ignition problems !! Without this <u>direct</u> connection the system does not work or not work for long without problems. Please do not rely on the frame for ground. Paint, oil and dirt often prevent good contact!</p>		
*		<p>The new regulator/rectifier has 4 wires</p> <ul style="list-style-type: none"> ■ 2 black ending in a plastic plug for the AC input from the 2 black generator wires ■ 1 red with a plastic plug which outputs plus ■ 1 brown with a plastic plug being ground (minus)

The two black cables leading from the generator should be first introduced into the supplied twin plastic plug housing. This housing connects to the plastic plug at the end of the 2 black wires on the regulator. It does not matter which black is at which side, as there is AC.
The brown cable from the regulator should connect to either battery minus or good ground if there is no battery.
The red cable from the regulator ... Take care: Wrong polarity will damage the electronics!	... should connect to either battery 12V PLUS or if there is no battery to the wiring that runs to your consumers (normally main switch intake pin).
If you use a battery, make sure that you have a 15A-fuse between battery and vehicle circuitry.	
There is NO facility for a charge control light without battery this will not work anyway. The regulator has an inbuilt high potency condenser to smoothen voltage. This will make sure that your side indicators (flashers) and horn will work correctly even without battery.	
* Remains the blue (sometimes blue/white) wire at the ignition coil. This is the kill (cut-off) wire. Note: Should you experience ignition failures, disconnect as a first measure this blue wire. In many cases that will permit you to get mobile again (particulars see: technical help)!	Connected to ground - it will stop ignition! This type of wiring is used in motorcycles which originally already had magneto ignition and therefore switched off by shortcircuiting against ground. Those vehicles have by design a main lock (or some kill switch) that connects a pin to ground when in OFF position (German bikes: pin 2). The blue(/white) wire of the ignition coil will be connected here. In that way the cut-off works like previously.
* Screw the high tension (ignition) cable ... Please do not use any spark amplifying cables, such as "Nology supercables" or "hot wire". This will disturb the system and possibly damage it.	... into the ignition coil and pull over the rubber seal before mounting the coil (it will be easier). Please do use the cable arriving with the pack and not any old cable.
You will do yourself a favour to treat your bike to new spark plugs and spark plug sockets (preferably some between 0-2kOhm). Plenty of problems are to be traced back to "apparently good" (even completely "brand-new") sparks plugs, terminals and cables. Do not use spark plugs with an intern suppression resistor. NGK (e.g.) offered such spark plugs coded with an "R" (for resistor).	
* Finally - and before installing the battery and before the first kickstart - please re-check carefully all connections and fitments against the wiring diagram. Do check battery and light bulbs for correct voltage (12V). Should something not work, please consult our trouble-shooting guide on our homepage. As a first step disconnect the blue wire from the coil and re-test.	
* IMPORTANT: During crank shaft repair the dynamo shaft is often machined and gets shorter. The result is a rotor sitting lower, possibly touching now with its rivets the stator coil. The result is a destroyed stator and ignition failure. For more detail and how to check see (online) here .	
Important safety and operating information	

#	<p>Safety first! Please observe the general health and safety regulations motor vehicle repair (MVR) as well as the safety information and obligations indicated by the manufacturer of your motorcycle.</p> <p>The timing marks on the material are for general guidance only during first installation. Please check after assembly by suitable means (stroboscope) that settings are correct to prevent damage to the engine or possibly even your health. You alone are responsible for the installation and the correctness of settings.</p>
#	<p>Ignition systems generate high tension! With our material right up to 40,000 Volts! This may, if handled carelessly, not only be painful, but outrightly dangerous. Please do keep a safe distance to the electrode of your spark plug and open high tension cables. Should you need to test spark firing, hold the spark plug socket securely with some well insulating material and push it firmly to solid ground of the engine block.</p> <p>Never pull sparkplug caps when engine is running. Wash your vehicle only with engine at standstill and ignition off.</p>
#	<p>Should you have received in the kit HT cables with a fixed rubber boot(which does not contain a resistor) you might have to use spark plugs with an inbuilt resistor (or replace the cap with one containing a resistor) to comply with your local laws.</p>
#	<p>After installation, please <u>check tightness of all screws, even those preinstalled</u>. If parts get loose during run, there will be inevitably damage to the material. We pre-assemble screws only loosely.</p>
#	<p>Give the newly installed system a chance to work, before you start to check and test values, or what is worse apply changes to it. Our parts have been checked before delivery to you. You will not be able to check much anyway. At any rate do refrain from measuring the electronic components (such as ignition coil, regulator and advance unit). You risk severe damage to the inner electronics there. You will not get any tangible results from the operation anyway. Bear in mind that also your carburetor, your spark plugs and spark plug sockets (even if completely new) might be the reason for malfunction. The general experience with our systems is that the carburetor will have to be re-adjusted to lower settings. Should the system not start after assembly, first disconnect the blue (or blue/white) cut-off wire directly at the ignition coil (or in some cases advance unit) to eliminate any malfunction in the cut-off circuitry. Check ground connections carefully, make sure there is a good electrical connection between frame and engine block.</p> <p>In case of troubles, please consult our Knowledge Base first before you send off the material to us for checking</p>
#	<p>The spark of classic, points based ignition systems has with about 10,000 Volts comparatively little energy and looks therefore yellow and fat (which however makes it highly visible). The spark from our system is a high energy spark with up to 40,000 Volts and therefore is needle thin focused in form, and blue in colour, which makes it not so visible. Furthermore you get spark only at kick-start operated speeds and not by pushing the kick-lever down slowly with your hand (as you might get with battery based ignitions).</p>
#	<p><u>Systems using a twin outlet ignition coils</u> have a few peculiarities. Please observe that during tests on one side, the other has either to be connected to an fitted spark plug or securely earthed/grounded. Otherwise there will be no spark on either side. Also with such open exits long and dangerous sparks may fly all over the coil.</p>
#	<p>Never do electric arc welding on the bike without completely disconnecting all parts containing semiconductors (ignition coil, regulator, advance) stator and rotor need not be taken off. The same is true for soldering. Before touching electronics disconnect the soldering iron from mains! Never use copper putty on spark plugs.</p>
#	<p>Electronics are very sensitive to wrong polarity. After work on the system, do check correct polarity of the battery and the regulator. Wrong polarity creates short circuits and will destroy the regulator, the ignition coil and the advance unit. As a rule, wiring will always be colour to colour. Instances, where colour jumps between wires are expressly mentioned in our instructions.</p>
#	<p>When you handle the new rotor, take care not to damage its magnets. Refrain from direct blows to the circumference of the rotor. When transporting never put the rotor over the stator. Observe our information relative to transport of the material.</p>

#	Do not use spark plug sockets with a resistance of more than 5kOhm. Better use 1 or 2kOhm ones. Bear in mind that spark plug sockets do age and thereby increase their internal resistance. Should an engine start up only when cold, a defective spark plug socket and/or spark plug is very probably the cause. In case of problems check high tension cables too. Never use carbon fibre HT-cables, never use so called "hot wires" which promise to increase spark.
#	It is a good idea to cover the rotor in a thin layer of oil to reduce the risk of corrosion.
#	Never use a claw puller or a hammer to disengage the rotor. Its magnets might become loose in the event. We offer a special puller for disengaging the new rotor again (see assembly instruction)!
#	Should the motorcycle not be in use for some longer period, please disconnect the battery (so existing) to prevent current bleeding through the diodes of the regulator. Though, even a disconnected battery will empty itself after a while.
#	Please do observe these remarks, but at the same time, don't be afraid of the installation process. Remember, that before you, thousands of other customers have successfully installed the system. <i>Enjoy driving your bike with its new electric heart!</i>
